

GWCT's Peter Thompson talking about Bees

Bee careful what you eat

A friend has just alerted me to this study and as it is "pollinator awareness week", I thought that I would share it with you. Although much more work needs to be done before scientists can be sure that this is yet another factor in the decline of bees and other pollinators, it does perhaps already demonstrate how contaminated our world has become.

"A new scientific study has found very high amounts of aluminium contamination in bees, raising the question of whether aluminium-induced cognitive dysfunction is playing a role in the decline of bumblebee populations.

Aluminium is the Earth's most ubiquitous ecotoxicant and is already known to be responsible for the death of fish in acid lakes, forest decline in acidified and nutrient impoverished catchments, and low crop productivity on acid sulphate soils. Now, a collaboration between Professors Chris Exley (Keele University) and Dave Goulson (University of Sussex) raises questions on the role of aluminium in the decline of the bumblebee.

Previous research had suggested that when bees forage for nectar they do not actively avoid nectar which contains aluminium. This prompted the suggestion by Exley and Goulson that bees may be accumulating aluminium within their life cycle.

Researchers at University of Sussex collected pupae from colonies of naturally foraging bumblebees and sent them to Keele University where their aluminium content was determined.

The pupae were found to be heavily contaminated with aluminium, with individual contents ranging from between and 13 and nearly 200 ppm. Smaller pupae had significantly higher contents of aluminium.

To put these aluminium contents in some context, a value of 3 ppm would be considered as potentially pathological in human brain tissue. While preliminary, these data have shown the significant accumulation of aluminium in at least one stage of the bumblebee life cycle and suggest the possibility of another stressor contributing to the decline in its numbers.

Professor Exley, a leading authority on human exposure to aluminium, from Keele University said: "It is widely accepted that a number of interacting factors are likely to be involved in the decline of bees and other pollinators – lack of flowers, attacks by parasites, and exposure to pesticide cocktails, for example.

GWCT's Peter Thompson talking about Bees

“Aluminium is a known neurotoxin affecting behaviour in animal models of aluminium intoxication. Bees, of course, rely heavily on cognitive function in their everyday behaviour and these data raise the intriguing spectre that aluminium-induced cognitive dysfunction may play a role in their population decline – are we looking at bees with Alzheimer’s disease?”

The research is published in PLOS ONE;
